
Internetworking with Sockets

Cross-host Interprocess Communication (IPC)

- ▶ Typically client-server model over network
- ▶ Server - Provides a service
- ▶ Server - Waits for clients to connect
- ▶ Clients - Connect to utilize the service
- ▶ Clients - Possibly more than one at a time

The Internet Protocol

- ▶ Each device in a network is assigned an IP address
- ▶ IPv4 32 bit, IPv6 128 bit
- ▶ Each device may host many services
- ▶ Accessing a service requires an IP,port pair
- ▶ Services you know of: ssh (port 22), http (port 80), DNS (port 53), DHCP

Common Service Use Cases

Browse the World Wide Web

- ▶ Each device has a static IP
- ▶ DNS used to translate `www.google.com` to `74.125.43.103`
- ▶ Contact service at `74.125.43.103` and port 80 (`http`)

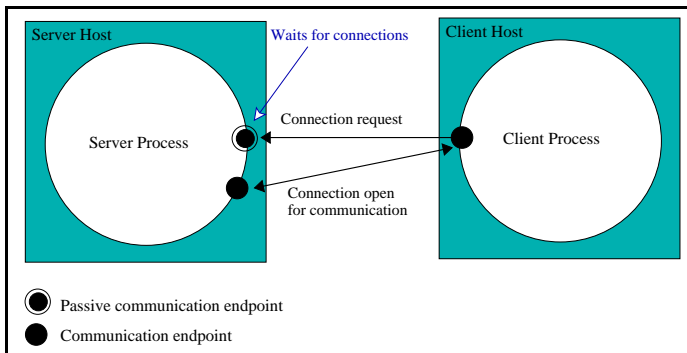

Common Service Use Cases

Your home network.

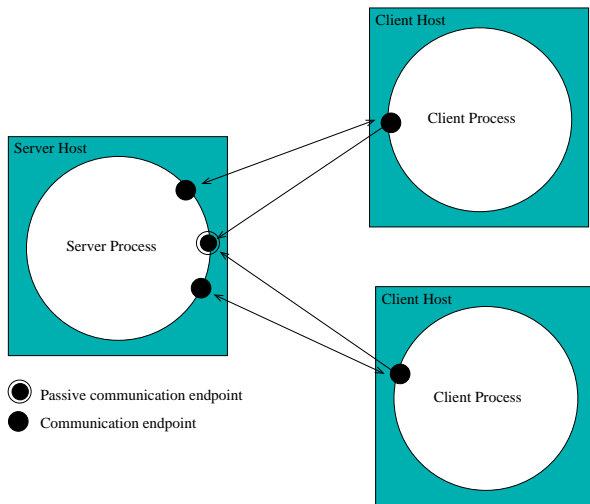

- ▶ You turn on your modem/router. It gets a public IP address from you ISP (e.g., 79.166.80.131)
- ▶ Your modem/router runs a DHCP server giving IPs in block 192.168.x.y
- ▶ Your modem/router acts as an Internet gateway. Translates IPs from 192.168.x.y to 79.166.80.131. IP Masquerade.
- ▶ What if you need to set up a service running inside your 192.168.x.y network available to the internet? Port forwarding.

The Transmission Control Protocol

- ▶ TCP uses acknowledgments
- ▶ Non-acknowledged messages are retransmitted
- ▶ Messages re-ordered by the receiver's OS network stack
- ▶ Application sees a properly ordered data stream

TCP - multiple clients

Sockets

- ▶ A *socket* is a communication endpoint
- ▶ Processes refer to a socket using an integer descriptor
- ▶ Communication domain
 - ▶ Internet domain (over internet)
 - ▶ Unix domain (same host)
- ▶ Communication type
 - ▶ Stream (usually TCP)
 - ▶ Datagram (usually UDP)

TCP vs UDP

	TCP	UDP
Connection Required	✓	✗
Reliability	✓	✗
Message Boundaries	✗	✓
In-Order Data Delivery	✓	✗
Socket Type	SOCK_STREAM	SOCK_DGRAM
Socket Domain	Internet	Internet
Latency	higher	lower
Flow Control	✓	✗

Serial Server (TCP)

Create listening socket a

loop

Wait for client request on a

Open two-way channel b with client

while request received through b **do**

 Process request

 Send response through b

end while

Close file descriptor of b

end loop

Drawbacks:

- ▶ Serves only one client at a time
- ▶ Other clients are forced to wait or even fail

1 process per client model

- ▶ New process forked for each client
- ▶ Multiple clients served at the same time
- ▶ Inefficient, too many clients → too many processes

1 process per client model

Parent process

Create listening socket a

loop

Wait for client request on a

Create two-way channel b with client

Fork a child to handle the client

Close file descriptor of b

end loop

Child process

Close listening socket a

Serve client requests through b

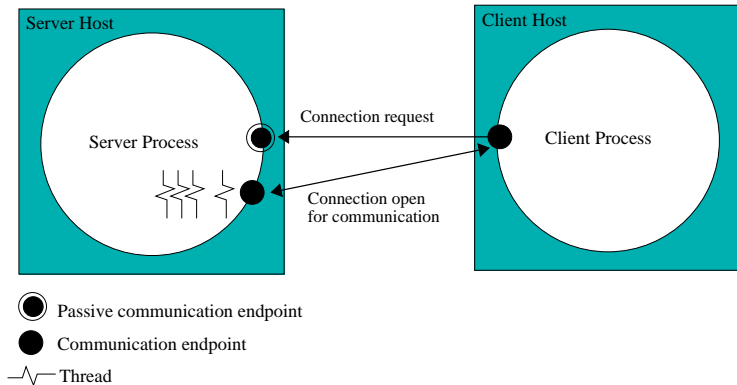

Close private channel b

Exit

Parent process: why close file descriptor *b*?

- ▶ Parent doesn't need this file descriptor
- ▶ Risk of running out of file descriptors otherwise
- ▶ Enables the destruction of the channel once the other two parties (child & client) close their file descriptors
- ▶ Enables the child process to receive EOF after the client closes its end of the channel (and vice versa).

Multithreaded server model

- ▶ Multiple threads handle multiple clients concurrently
- ▶ Drawback: Requires synchronization for access to shared resources

Dealing with byte order

- ▶ Byte order poses a problem for the communication among different architectures.
- ▶ Convention: ip addresses, port numbers etc. in *Network Byte Order*
- ▶ Convert long/short integers between *Host* and *Network* byte order

```
uint32_t htonl(uint32_t hostlong);  
uint16_t htons(uint16_t hostshort);  
uint32_t ntohl(uint32_t netlong);  
uint16_t ntohs(uint16_t netshort);
```

From Domain Names to Addresses and back

- ▶ An *address* is needed for network communication
- ▶ We often have to *resolve* the address from a domain name.
ex. spiderman.di.uoa.gr ↔ 195.134.66.107

```
struct hostent {
    char    *h_name;      /* official name of host */
    char    **h_aliases; /* aliases (alt. names) */
    int     h_addrtype; /* usually AF_INET */
    int     h_length;   /* bytelength of address */
    char    **h_addr_list; /* list of addresses */
};
struct hostent *gethostbyname(const char *name);
struct hostent *gethostbyaddr(const void *addr, socklen_t
    len, int type);
```

- ▶ Beware, both use static storage for struct hostent. (problem?)
- ▶ For error reporting use herror & hstrerror

Our goal

Create the communication endpoint. Use it as a file descriptor.

Server Process

Client Process

request for connection establishment

request

response

Creating sockets

- ▶ *socket* creates an endpoint for communication
- ▶ returns a descriptor or -1 on error

```
#include <sys/socket.h>
#include <sys/types.h>

int socket(int domain, int type, int protocol);
```

domain communication domain (usual. PF_INET)

type communication semantics (usual. SOCK_STREAM,
SOCK_DGRAM)

protocol Use 0 as typically only one protocol is available

```
if ((sock = socket(PF_INET, SOCK_STREAM, 0)) == -1)
    perror("Socket creation failed!");
```

Binding sockets to addresses

- ▶ *bind* requests for an address to be assigned to a socket
- ▶ You must bind a SOCK_STREAM socket to a local address before receiving connections

```
int bind(int socket, const struct sockaddr *address, socklen_t address_len);
```

Internet domain (AF_INET):

- ▶ We pass a *sockaddr_in* struct as the *address*

Interesting fields:

`sin_family` address family is AF_INET in the internet domain

`sin_addr.s_addr` address can be a specific IP or INADDR_ANY

`sin_port` TCP or UDP port number

Socket binding example

```
#include <netinet/in.h> /* for sockaddr_in */
#include <sys/socket.h>
#include <sys/types.h>
#include <arpa/inet.h> /* for hton* */

int bind_on_port(int sock, short port) {
    struct sockaddr_in server;
    server.sin_family = AF_INET;
    server.sin_addr.s_addr = htonl(INADDR_ANY);
    server.sin_port = htons(port);
    return bind(sock, (struct sockaddr *) &server, sizeof(
        server));
}
```

- ▶ INADDR_ANY is a special address (0.0.0.0) meaning “any address”
- ▶ sock will receive connections from all addresses of the host machine

listen, accept

```
int listen(int socket, int backlog);
```

- ▶ Listen for connections on a socket
- ▶ At most *backlog* connections will be queued waiting to be accepted

```
int accept(int socket, struct sockaddr *address, socklen_t *address_len);
```

- ▶ Accept a connection on a socket
- ▶ Blocks until a client connects or interrupted by signal
- ▶ Returns new socket descriptor used to communicate with client
- ▶ Returns info on client's address through *address*. Pass NULL if you don't care.
- ▶ Value-result *address_len* must be set to the amount of space pointed to by *address* (or NULL).

connect

```
int connect(int socket, struct sockaddr *address, socklen_t
address_len);
```

- ▶ When called by a client, a connection is attempted to a listening socket on the server in *address*. Normally, the server *accepts* the connection and a communication channel is established.
- ▶ If *socket* is of type `SOCK_DGRAM`, *address* specifies the peer with which the socket is to be associated (datagrams are sent/received only to/from this peer).

TCP connection

Server Process

Client Process

request for connection establishment

request

response

Tips and warnings

- ▶ In Solaris compile with “-lsocket -lnsl”
- ▶ If a process attempts to write through a socket that has been closed by the other peer, a SIGPIPE signal is received.
- ▶ SIGPIPE is by default fatal, install a signal handler to override this.
- ▶ Use *netstat* to view the status of sockets.

```
ad@linux03 :~> netstat -ant
```

- ▶ When a server quits, the listening port remains busy (state TIME_WAIT) for a while
- ▶ Restarting the server fails in bind with “Bind: Address Already in Use”
- ▶ To override this use *setsockopt()* to enable SO_REUSEADDR

TCP server that receives a string and replies with the string capitalized.

```
/*inet_str_server.c: Internet stream sockets server */
#include <stdio.h>

}

```

TCP client example. (definitions)

```
/* inet_str_client.c: Internet stream sockets client */
#include <stdio.h>
#include <sys/types.h>           /* sockets */
#include <sys/socket.h>         /* sockets */
#include <netinet/in.h>        /* internet sockets */
#include <unistd.h>             /* read, write, close */
#include <netdb.h>              /* gethostbyaddr */
#include <stdlib.h>             /* exit */
#include <string.h>             /* strlen */

void perror_exit(char *message);

void main(int argc, char *argv[]) {
    int          port, sock, i;
    char         buf[256];
    struct sockaddr_in server;
    struct sockaddr *serverptr = (struct sockaddr*)&server;
    struct hostent *rem;
    if (argc != 3) {
        printf("Please give host name and port number\n");
        exit(1);}
}
```

TCP client example. (connection)

```
/* Create socket */
if ((sock = socket(PF_INET, SOCK_STREAM, 0)) < 0)
    perror_exit("socket");
/* Find server address */
if ((rem = gethostbyname(argv[1])) == NULL) {
    perror("gethostbyname"); exit(1);
}
port = atoi(argv[2]); /*Convert port number to integer*/
server.sin_family = AF_INET; /* Internet domain */
memcpy(&server.sin_addr, rem->h_addr, rem->h_length);
server.sin_port = htons(port); /* Server port */
/* Initiate connection */
if (connect(sock, serverptr, sizeof(server)) < 0)
    perror_exit("connect");
printf("Connecting to %s port %d\n", argv[1], port);
```

TCP client example. (transfer loop)

```
do {
    printf("Give input string: ");
    fgets(buf, sizeof(buf), stdin); /* Read from stdin*/
    for(i=0; buf[i] != '\0'; i++) { /* For every char */
        /* Send i-th character */
        if (write(sock, buf + i, 1) < 0)
            perror_exit("write");
        /* receive i-th character transformed */
        if (read(sock, buf + i, 1) < 0)
            perror_exit("read");
    }
    printf("Received string: %s", buf);
} while (strcmp(buf, "END\n") != 0); /* Finish on "end" */
close(sock); /* Close socket and exit */
}

void perror_exit(char *message)
{
    perror(message);
    exit(EXIT_FAILURE);
}
```

Execution

Server on linux02:

```
ad@linux02:~> ./server 9002
Listening for connections to port 9002
Accepted connection from linux03.di.uoa.gr
Hello world
EnD
Closing connection.
```

Client on linux03:

```
ad@linux03:~> ./client linux02.di.uoa.gr 9002
Connecting to linux02.di.uoa.gr port 9002
Give input string: Hello world
Received string: HELLO WORLD
Give input string: EnD
Received string: END
ad@linux03:~>
```

More useful functions

shutdown shut down part of a full-duplex connection

```
int shutdown(int socket, int how);
```

Can be used to tell server that we have sent the whole request.

getsockname get the current address of a socket

```
int getsockname(int socket, struct sockaddr *  
address, socklen_t *address_len);
```

getpeername get the name (address) of the peer connected to socket. (inverse of getsockname)

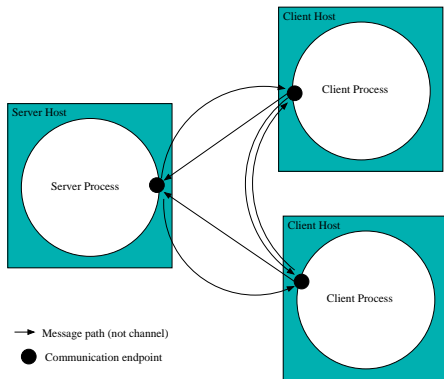

```
int getpeername(int socket, struct sockaddr *  
address, socklen_t *address_len);
```

Parsing and Printing Addresses

- `inet_ntoa` Convert struct `in_addr` to printable form 'a.b.c.d'
- `inet_addr` Convert IP address string in '.' notation to 32bit network address
- `inet_ntop` Convert address from network format to printable presentation format
- `inet_pton` Convert presentation format address to network format

Bonus: `inet_ntop` and `inet_pton` also work with IPv6!

Internet User Datagram Protocol (UDP)

- ▶ no connections. Think postcards, not telephone.
- ▶ *Datagrams* (messages) exchanged.
- ▶ Datagrams get lost or arrive out of order

UDP communication

sendto, recvfrom

```
ssize_t sendto(int sock, void *buff, size_t length,  
int flags, struct sockaddr *dest_addr, socklen_t dest_len);
```

- ▶ Send a message from a socket
- ▶ Similar to write() & send() (which we haven't seen) but allows to specify destination

```
ssize_t recvfrom(int socket, void *buff, size_t length,  
int flags, struct sockaddr *addr, socklen_t *address_len);
```

- ▶ Receive a message from a socket
- ▶ Similar to read() & recv() (which we haven't seen) but allows to get the source address
- ▶ address_len is value-result and must be initialized to the size of the buffer pointed to by the address pointer
- ▶ last two arguments can be NULL

Usually flags = 0. Rarely used (e.g., Out Of Band data)

A simple echoing UDP server

Client on linux03 (needs to be given the server's port#):

```
ad@linux03:~> fortune | ./inet_dgr_client linux02 59579
Hlade's Law:
    If you have a difficult task, give it to a lazy person
    --
    they will find an easier way to do it.
ad@linux03:~>
```

Server on linux02:

```
ad@linux02:~> ./inet_dgr_server
Socket port: 59579
Received from linux03: Hlade's Law:
Received from linux03:  If you have a difficult task, give
    it to a lazy person --
Received from linux03:  they will find an easier way to do
    it.
```

```

connectives
propernames
web2
web2a
words
ad@linux03:~>
```

rlsd.c remote ls server with paranoia (TCP)

Demonstrates interesting calls

`fdopen` allows buffered I/O by opening socket as file stream

`popen` pipe+fork+execute command together

```
/* rlsd.c - a remote ls server - with paranoia */
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <netdb.h>
#include <time.h>
#include <string.h>
#include <ctype.h>
#define PORTNUM 15000 /* rlsd listens on this port */

void perror_exit(char *msg);
void sanitize(char *str);
```

```

int main(int argc, char *argv[]) {
    struct sockaddr_in myaddr; /* build our address here */
    int c, lsock, csock; /* listening and client sockets */
    FILE *sock_fp; /* stream for socket IO */
    FILE *pipe_fp; /* use popen to run ls */
    char dirname[BUFSIZ]; /* from client */
    char command[BUFSIZ]; /* for popen() */

    /** create a TCP a socket **/
    if ((lsock = socket( PF_INET, SOCK_STREAM, 0)) < 0)
        perror_exit( "socket" );
    /** bind address to socket. **/
    myaddr.sin_addr.s_addr = htonl(INADDR_ANY);
    myaddr.sin_port = htons(PORTNUM); /*port to bind socket*/
    myaddr.sin_family = AF_INET; /* internet addr family */
    if(bind(lsock, (struct sockaddr*)&myaddr, sizeof(myaddr)))
        perror_exit( "bind" );
    /** listen for connections with Qsize=5 **/
    if ( listen(lsock, 5) != 0 )
        perror_exit( "listen" );

```

```

while ( 1 ){ /* main loop: accept - read - write */
    /* accept connection, ignore client address */

`rls.c` sends a directory name to `rlsd` and reads back a directory listing (TCP)

`write_all` guarantees to send all the bytes requested, provided no error occurs, by repeatedly calling `write()`

```
#include <sys/types.h> /* sockets */
#include <sys/socket.h> /* sockets */
#include <netinet/in.h> /* internet sockets */
#include <netdb.h> /* gethostbyname */
#define PORTNUM 15000
#define BUFSIZE 256
void perror_exit(char *msg);

/* Write() repeatedly until 'size' bytes are written */
int write_all(int fd, void *buff, size_t size) {
    int sent, n;
    for(sent = 0; sent < size; sent+=n) {
        if ((n = write(fd, buff+sent, size-sent)) == -1)
            return -1; /* error */
    }
    return sent;
}
```

```

int main(int argc, char *argv[]) {
    struct sockaddr_in servadd; /* The address of server */
    struct hostent *hp;        /* to resolve server ip */
    int sock, n_read;         /* socket and message length */
    char buffer[BUFSIZE];     /* to receive message */

    if ( argc != 3 ) {
        puts("Usage: rls <hostname> <directory>");exit(1);}
    /* Step 1: Get a socket */
    if ((sock = socket(PF_INET, SOCK_STREAM, 0)) == -1 )
        perror_exit( "socket" );
    /* Step 2: lookup server's address and connect there */

}
```

The ROCK PAPER SCISSORS game

- ▶ One referee process.
- ▶ Two players: a local process (playing random), a remote process (accepting input)
- ▶ Referee talks to the local process through pipes
- ▶ Referee talks to the remote process through sockets
